More people are beginning to consider the benefits of C++11, and others are already using it. While there are many enhancements in the C++11 standard, one of the most sought after and useful features is the threading support that is made available for the entire standard C++ library (STL). This post is the first in a series that will cover the basics of threading and the standard library using the C++11 threading facilities. If you'd prefer, you can continue to use older methods to implement threading or wait for a future post to cover newer techniques using Boost. The threading support in the STL is fairly straightforward to implement in a C++03-compatible fashion and is also compatible with other programming languages (such as Java) that also support threading. In this blog post, I'll walk through some of the basic concepts in constructing your own C++11 threading solution. The Basics of Threading Threading is not entirely new to C++. It has been a part of C++ since the first standard (C++98) and, in fact, was originally implemented by GCC. While the work on threading support in C++ is in many ways similar to that of C++98, C++11 adds some important enhancements to the standard library. The most important of these is the thread class, which will be covered in greater detail in my next post. The thread class contains many of the threading concepts that are covered in C++11. To get an understanding of how the thread class works, let's begin by looking at the concept of objects. Objects in C++11 can be a bit different than objects from previous versions of C++. For example, C++11 supports reference types, which cannot be passed by value to methods in previous versions of C++, while not actually being reference types themselves. The standard defines a basic value object as an object which is considered to be a value. For example, a variable or parameter in a method can be considered to be a value. This is covered in more detail in the next post. Because of this type of object, the C++11 standard also defines the concept of a reference type, or rvalue. A reference type is an object, such as a class or struct, which is considered an lvalue or value to the compiler or an object that can be used to call methods on another object. These reference types can be sent by value to a
