I use the answer to a previous question to put static resources like css in a separate folder in my source. However I have a situation where I have classes in a namespace that I don't want to expose to users. Is there a way to explicitly bind the entire namespace of a class to another namespace? A: The answer to your question is no. You would need to split your code across the class and namespace boundaries. This is a case where some sort of external configuration would be very helpful to the development team. Imagine you have the code namespace MyNamespace { public class MyClass { public void DoSomething() { //Do some stuff and update static resources } } } and your code base is under your source control. You go to your code base root and you see something like this. MyNamespace.MyClass Can't access MyClass. Do you need to expose this code to your clients? Clients will want to access the MyClass. This code access directly to the class and you might not want to expose that directly. If you expose it, you would need to go and change all references from MyNamespace.MyClass to MyNamespace.MyClass. This leads to two solutions. You can either change the source code and make the refactoring (my choice). Or you can introduce a coding convention that "Do not directly access the implementation detail" but then the developers would have to follow the coding conventions. Personally, I would go for the second solution as a simple coding

Supramolecular nanopores are created from self-assembled amylose nanofibrils (AFs) that possess thermoresponsive properties. AFs are a newly developed chiral fibrillated cellulose that exhibit attractive properties such as high mechanical strength, good biocompatibility, and biodegradability. The thermal transition of AFs causes a phase transition, which can be exploited to create supramolecular nanopores in AFs. AFs exhibit different diameter sizes and widths of AF pore walls as a function of their transition temperature. The AFs in the porous state at a high temperature are subjected to a mechanical shear, which causes them to uniaxially align and self-assemble into nanopores. In contrast, AFs in the porous state at a low temperature are not subjected to a mechanical shear, and remain unaligned. A hydrophobic polystyrene nanoparticle (NPs) suspension is used as a model system, and the direction of NP entrapment into the pore is determined by the transition temperature of the AF. The self-assembled AFs are optically transparent and exhibit the lowest optical scattering at a low temperature (0-20 °C). The AFs are shown to efficiently entrap Au and Pt NPs with controlled size distribution. Transmission electron microscopy images reveal that NPs are located around the pore wall of the AF nanopore. The coated NPs are subsequently embedded in various thermoresponsive surfaces, which are used to determine the size and morphology of the AF nanopores.The potential of bovine leukocyte interferon for the treatment of human AIDS. We studied the immunorestorative capacity of bovine leukocyte interferon (BLI) in 12 human immunodeficiency virus (HIV)-infected patients receiving neither antiretroviral treatment nor BLI therapy. Treatment with BLI was given for four to 42
