solutions for a patient. There has been significant interest in developing methods and devices for removing contaminants from solutions. For example, where solutions are dialysate or infusion solutions, such as those used in automated peritoneal dialysis, it has been found that the removal of contaminants from the solutions is greatly enhanced by devices and methods that efficiently maximize the surface area contacting the solution. Such solutions are usually required to have a chloride concentration of less than 50 millimoles/liter. For example, U.S. Pat. No. 4,852,568 (McIntyre et al., 10 Nov. 1989) discloses a dialysate filter having a filter unit with millions of fine porous beads that completely fill the void spaces in the filter unit. The filter unit includes multiple filtrate chambers arranged along at least a portion of its length. Blood flows through the filter unit and into the

filtrate chambers. Dialysate flows in an opposite direction around the beads and through the filtrate chambers.

Several drawbacks exist with the current systems for removing contaminants from dialysis solutions, for example. In general, dialysis solutions often require a very small volume, for example about 15 to about 100 milliliters. This limits the amount of surface area from which contaminants can be removed, and thus, there is a need to increase the surface area contacting the solution. Further, especially in small dialysis systems, the amount of dialysate flow is limited. This limits the amount of surface area available for contaminants removal, and thus, there is a need to maximize this surface area. Additionally, the current systems for removing contaminants from dialysis solutions do not allow for efficient cleaning of the systems. Often, cleaning procedures
